Art Unit: 1763

DETAILED ACTION

Election/Restrictions

Applicant's election with traverse of group I in the reply filed on 8/8/05 is acknowledged. The traversal is on the ground(s) that there is no undue burden placed upon the examiner. This is not found persuasive because there is an undue burden placed upon the examiner because of the multiple species. Furthermore, if a generic claim is found allowable, all dependent claims from the generic claim will also be found allowable.

The requirement is still deemed proper and is therefore made FINAL.

Newly submitted claim 69 is directed to an invention that is independent or distinct from the invention originally claimed for the following reasons: the invention represented by claim 69 is a subcombination of the invention represented by the rest of the pending claims. Restriction is proper because the impedance matching layer of the combination does not need to be symmetrical and circumferential and the impedance matching layer of the subcombination could be utilized, for example, in a different apparatus than the combination (note that claim 69 is mainly a claim directed to intended use)

Since applicant has received an action on the merits for the originally presented invention, this invention has been constructively elected by original presentation for prosecution on the merits. Accordingly, claim 69 is withdrawn from consideration as being directed to a non-elected invention. See 37 CFR 1.142(b) and MPEP § 821.03.

Art Unit: 1763

Claim Rejections - 35 USC § 102

The following is a quotation of the appropriate paragraphs of 35 U.S.C. 102 that form the basis for the rejections under this section made in this Office action:

A person shall be entitled to a patent unless -

- (b) the invention was patented or described in a printed publication in this or a foreign country or in public use or on sale in this country, more than one year prior to the date of application for patent in the United States.
- (e) the invention was described in (1) an application for patent, published under section 122(b), by another filed in the United States before the invention by the applicant for patent or (2) a patent granted on an application for patent by another filed in the United States before the invention by the applicant for patent, except that an international application filed under the treaty defined in section 351(a) shall have the effects for purposes of this subsection of an application filed in the United States only if the international application designated the United States and was published under Article 21(2) of such treaty in the English language.

Claims 48-49 and 54 are rejected under 35 U.S.C. 102(b) as being anticipated by Ohmi et al., WO 98/39500.

Ohmi et al. shows the invention as claimed including a uniformity mechanism suitable for use in a process chamber within which a plasma is ignited and sustained for processing a substrate 108, the uniformity mechanism comprising: a first zone 101a configured to be disposed underneath a first region of the substrate, the first zone having a first impedance when energy is coupled therethrough (through, first component, electrode 101); a second zone (the outer periphery of zone 101a which is the part of electrode 101 that is not in contact with the substrate) configured to be disposed underneath a second region of the substrate, the second zone having a second impedance when energy is coupled therethrough (second component, edge ring 103), the second impedance being different than the first impedance; and an impedance matching layer 104 positioned within the second zone and having characteristics

Art Unit: 1763

configured to adjust the second impedance, the characteristics including at least one of a thickness, a length, position, or a material property, and wherein the impedance matching layer is disposed below the second component (see, for example, figs. 1, 6A, 6B, 7B, 9, 26A-26I, and their descriptions). With respect to claim 54, nee that the uniformity mechanism includes a third component 105 for generating an electric field.

Claims 22-23, 25, 27-31, 48-49, 51-55, 60-61, 63, and 65-66 are rejected under 35 U.S.C. 102(b) as being anticipated by Masuda et al., U.S. Patent 6,171,438.

Masuda et al. shows the invention substantially as claimed including a pedestal for supporting a substrate W during plasma processing, the pedestal comprising: an electrode 130 configured generating an electric field; a chuck 131 disposed above the electrode, the chuck being configured for holding the substrate and having an outer periphery that is smaller than an outer periphery of the substrate (see fig. 2); a dielectric edge ring 133 disposed above the electrode, the edge ring being configured for shielding the electrode and the chuck, and including a first portion configured to be disposed between the electrode and the substrate when the substrate is held by the chuck (and configured to surround an outer edge of the chuck) and a second portion being configured to surround an outer edge of the substrate when the substrate is held by the chuck for processing whereby the edge ring cooperated with the chuck to form a recessed portion for accepting the substrate for processing (see fig. 2); and an impedance matching layer 132 disposed between the electrode and the edge ring, and underneath said substrate when said substrate is resting on said pedestal, said

impedance matching layer being entirely planar and parallel with a top surface of the electrode and a bottom surface of the edge ring, the impedance matching layer made of a dielectric material such as quartz. It should be noted that the impedance matching layer 132 will control the impedance between the electrode and the plasma and will reduce the variations of the electric field so that the impedance produced through the edge ring is substantially equal to the first impedance produced through the chuck (note that the word substantially can be interpreted broadly). For a complete description, see for example, figs. 1-2 and their descriptions).

Concerning claims 49, 53 and 54-55, note that the first component is the chuck, the second component is the edge ring, and the third component is the electrode.

With respect to claims 60-61 and 63, note that: a) the electrode is formed of a conductive material and the chuck, the edge ring and the impedance matching layer are made of dielectric material, b) the edge ring and the chuck can be made of the same material such as alumina and the impedance matching layer can be made of a material having a larger dielectric constant such as SiC, and c) the impedance matching layer can be made of materials including the claimed materials, (see, for example, col. 8. lines 44-63). Regarding claim 65, note that as broadly claimed the substrate region can be considered to be any region within the region of the lower electrode 130.

Concerning claim 66, the top surface of the electrode is configured to be substantially uniform and substantially parallel to the substrate so as to provide an even distribution of energy.

Art Unit: 1763

Claims 22-23, 25, 27-31, 48-49, 51-55, 63, and 65-66 are rejected under 35 U.S.C. 102(b) as being anticipated by Wicker et al., U.S. Patent 6,129,808.

Wicker et al. shows the invention substantially as claimed including a pedestal for supporting a substrate 104 during plasma processing, the pedestal comprising: an electrode 108 configured generating an electric field; a chuck 106 disposed above the electrode, the chuck being configured for holding the substrate and having an outer periphery that is smaller than an outer periphery of the substrate (see fig. 2); a dielectric edge ring 114 being entirely planar and parallel and disposed above the electrode, the edge ring being configured for shielding the electrode and the chuck, and including a first portion configured to be disposed between the electrode and the substrate when the substrate is held by the chuck (and configured to surround an outer edge of the chuck) and a second portion being configured to surround an outer edge of the substrate when the substrate is held by the chuck for processing whereby the edge ring cooperated with the chuck to form a recessed portion for accepting the substrate for processing (see fig. 1); and an impedance matching layer 112 disposed between the electrode and the edge ring, the impedance matching layer made of a dielectric material such as SiC. It should be noted that the impedance matching layer 112 will control the impedance between the electrode and the plasma and will reduce the variations of the electric field. For a complete description, see for example, fig. 1 and its description).

Concerning claims 49, 53 and 54-55, note that the first component is the chuck, the second component is the edge ring, and the third component is the electrode.

Art Unit: 1763

With respect to claims 60-61 and 63, note that the impedance matching layer can be made of materials including the claimed materials, (see, for example, col. 6. lines 16-23). Regarding claim 65, note that as broadly claimed the substrate region can be considered to be any region within the region of the lower electrode.

Concerning claim 66, the top surface of the electrode is configured to be substantially uniform and substantially parallel to the substrate so as to provide an even distribution of energy.

Claim Rejections - 35 USC § 103

The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:

(a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negatived by the manner in which the invention was made.

This application currently names joint inventors. In considering patentability of the claims under 35 U.S.C. 103(a), the examiner presumes that the subject matter of the various claims was commonly owned at the time any inventions covered therein were made absent any evidence to the contrary. Applicant is advised of the obligation under 37 CFR 1.56 to point out the inventor and invention dates of each claim that was not commonly owned at the time a later invention was made in order for the examiner to consider the applicability of 35 U.S.C. 103(c) and potential 35 U.S.C. 102(e), (f) or (g) prior art under 35 U.S.C. 103(a).

Art Unit: 1763

Claims 22-23, 25, 27-32, 34-37, 39, 41-43, 47-49, 51-55 and 65-67 are rejected under 35 U.S.C. 103(a) as being unpatentable over Tamura et al., U.S. Patent 5,792,304 in view of Ohmi et al., WO 98/39500.

Tamura et al. shows the invention substantially as claimed including a pedestal for supporting a substrate 1 during plasma processing, the pedestal comprising: an electrode 2 configured generating an electric field (see, for example, fig. 9 and col. 14, line 44-52); a chuck disposed above the electrode, the chuck being configured for holding the substrate and having an outer periphery that is smaller than an outer periphery of the substrate (see, for example, fig. 9 and col. 14, line 44-52); a dielectric edge ring 36 disposed above the electrode, the edge ring being configured for shielding the electrode and the chuck, and including a first portion configured to be disposed between the electrode and the substrate when the substrate is held by the chuck (and configured to surround an outer edge of the chuck) and a second portion being configured to surround an outer edge of the substrate when the substrate is held by the chuck for processing whereby the edge ring cooperated with the chuck to form a recessed portion for accepting the substrate for processing. For a complete description, see for example, fig. 9 and its description).

Tamura et al. does not expressly disclose the claimed impedance matching layer disposed between the electrode and the edge ring. Ohmi et al., as described above, discloses an apparatus comprising a pedestal for supporting a substrate 108 during plasma processing, the pedestal including an impedance matching layer 104 disposed between an electrode 101 and an edge ring 103, the impedance matching layer made

Art Unit: 1763

of a dielectric material and has characteristics configured for controlling an impedance between the electrode and a plasma in order to improve the processing uniformity across the surface of the substrate and make impedances substantially equal at different regions underneath the substrate (see, for example, figs. 1, 6A, 6B, 7B, 9, 26A-26I, and their descriptions). Therefore, it would have been obvious to one having ordinary skill in the art at the time the invention was made to modify the pedestal of the Tamura et al. as to comprise an impedance matching layer disposed between the electrode and the edge ring, as taught by Ohmi et al., in order to improve the processing uniformity across the surface of the substrate and thereby optimizing the apparatus.

With respect to claims 23, 25, 27, the impedance matching layer of the apparatus of Tamura et al. modified by Ohmi et al., will reduce variations in the electric field, is arranged to control the impedance between the electrode and the plasma at the edge of the substrate, is configured to be disposed between the electrode and the substrate when the substrate is held by the chuck. Regarding claim 32, the chuck, edge ring and impedance matching layer are formed from a dielectric material, wherein the dielectric constant of the edge ring may be equal to the dielectric constant of the chuck (note that both the chuck and the edge ring can be made of Al2O3), and wherein the dielectric constant of the impedance matching layer may be different than the dielectric constant of the edge ring and the chuck. Furthermore and with respect to claim 33, it should be noted that a first impedance produced through the chuck is different than a second impedance produced through the edge ring, and wherein the impedance matching layer may be arranged to adjust the second impedance produce through the edge ring so that

the second impedance is substantially equal to the first impedance produced through the chuck.

With respect to claim 34, note that the chuck is disposed in an inner region of the electrode, the edge ring is disposed above the outer region of the electrode and positioned next to a side of the chuck, and the impedance matching layer is disposed between the edge ring and the electrode and above the outer region of the electrode.

Regarding claims 36-37 and 41, note that the impedance matching layer of the apparatus of Tamura et al. modified by Ohmi et al., is bonded to both the edge ring and the electrode by screw 112, the electrode has an outer periphery that is greater than the outer periphery of the substrate when the substrate is disposed on the chuck for processing.

Regarding claims 49, 53 and 54-55, note in the pedestal of Tamura et al. modified by Ohmi et al., the first component is the chuck, the second component is the edge ring, and the third component is the electrode.

Regarding claim 65, note that as broadly claimed the substrate region can be considered to be any region within the region of the lower electrode.

With respect to the impedance matching layer being bonded to the edge ring through a silicon elastomer, it would have been obvious to one of ordinary skill in the art at the time the invention was made to bond these elements through a silicon elastomer because this is a well established means of bonding elements in a plasma processing apparatus.

Art Unit: 1763

Claims 44-45, 60-61, 63, and 68 are rejected under 35 U.S.C. 103(a) as being unpatentable over Tamura et al., U.S. Patent 5,792,304 in view of Ohmi et al., WO 98/39500 as applied to claims 22-23, 25, 27-32, 34-37, 39, 41-43, 47-49, 51-55 and 65-67 above, and further in view of Masuda et al., U.S. Patent 6,171,438.

Tamura et al. and Ohmi et al. are applied as above but do not expressly disclose a heat transfer system as claimed. Masuda et al. discloses a plasma processing apparatus comprising a pedestal including a heat transfer system for controlling the temperature of the substrate and the edge ring during processing, the heat transfer system including a first channel extending through the electrode to the interface. between the chuck and the substrate, and a second channel extending through the electrode to the interface between the electrode and the edge ring, the heat transfer system being configured to provide a heat transfer medium though the channels, wherein the heat transfer is a helium gas (see fig. 2 and its description). Therefore, in view of this disclosure, it would have been obvious to one having ordinary skill in the art at the time the invention was made to modify the apparatus of Tamura et al. modified by Ohmi et al. as to comprise the heat transfer system disclosed by Masuda et al. because this allows for effective and efficient temperature control of the substrate and the edge ring without incorporating a complicated mechanism.

Tamura et al. and Ohmi et al. are applied as above but do not expressly disclose the claimed limitation of claims 60-61 and 63. Masuda et al., as described above, discloses an apparatus comprising a pedestal having an electrode formed of a conductive material and the edge ring, the chuck and the impedance matching layer are

Art Unit: 1763

made of a dielectric material (see, for example, col. 8. lines 44-63). Therefore, in view of this disclosure, it would have been obvious to one having ordinary skill in the art at the time the invention was made to modify the apparatus of Tamura et al. modified by Ohmi et al. as to comprise an electrode, a chuck, an edge ring and the impedance matching layer made of the claimed material because such materials are known to be suitable material. Note that Masuda teaches that the edge ring and the chuck can be made of the same material such as alumina and the impedance matching layer can be made of a material having a larger dielectric constant such as SiC.

Claims 32, 34-37, 39, 41-45, 47, and 67-68 are rejected under 35 U.S.C. 103(a) as being unpatentable over Masuda et al., U.S. Patent 6,171,438.

Masuda et al. shows the invention substantially as claimed including a pedestal for supporting a substrate W during plasma processing, the pedestal comprising: an electrode 130 configured generating an electric field; a chuck 131 disposed above the electrode, the chuck being configured for holding the substrate and having an outer periphery that is smaller than an outer periphery of the substrate (see fig. 2); an edge ring 133 disposed above the electrode, the edge ring being configured for shieldin9g the electrode and the chuck, and including a first portion configured to be disposed between the electrode and the substrate when the substrate is held by the chuck (and configured to surround an outer edge of the chuck) and a second portion being configured to surround an outer edge of the substrate when the substrate is held by the chuck for processing whereby the edge ring cooperated with the chuck to form a recessed portion

Art Unit: 1763

for accepting the substrate for processing (see fig. 2); and an impedance matching layer 132 disposed between the electrode and the edge ring, the impedance matching layer made of a dielectric material such as quartz. It should be noted that the impedance matching layer 132 will control the impedance between the electrode and the plasma and will reduce the variations of the electric field. Furthermore, note that the chuck is disposed in an inner region of the electrode, the edge ring is disposed above the outer region of the electrode and positioned next to a side of the chuck, and the impedance matching layer is disposed between the edge ring and the electrode and above the outer region of the electrode. For a complete description, see for example, figs. 1-2 and their descriptions).

Masuda et al. further discloses that the chuck, the edge ring and the impedance matching layer are made of a dielectric material, but does not expressly disclose that the dielectric constant of the edge ring is equal to the dielectric constant of the chuck, wherein the dielectric constant of the impedance matching layer is different than the dielectric constant of the edge ring and the chuck, and wherein the impedance matching layer is arranged to adjust an impedance produced through the edge ring so that it is substantially the same impedance as an impedance produced through the chuck. However, it would have been an obvious choice of design to one having ordinary skill in the art at the time the invention was made to choose the same or different materials for the chuck, the edge ring and the impedance matching layer based upon a variety of factors, including for example, the plasma resistance of the material, and such limitation

Art Unit: 1763

would not lend patentability to the instant invention absent the showing of unexpected results.

Regarding claims 36-37 and 41, note that the impedance matching layer is bonded to both the edge ring and the electrode, the electrode has an outer periphery that is greater than the outer periphery of the substrate when the substrate is disposed on the chuck for processing.

Regarding claims 44-45, note that Masuda et al. discloses such heat transfer system (see fig. 2 and its description).

With respect to the impedance matching layer being bonded to the edge ring through a silicon elastomer, it would have been obvious to one of ordinary skill in the art at the time the invention was made to bond these elements through a silicon elastomer because this is a well established means of bonding elements in a plasma processing apparatus.

Claims 32, 34-37, 39, 41-43, 47, and 67 are rejected under 35 U.S.C. 103(a) as being unpatentable over Wicker et al., U.S. Patent 6,129,808.

Wicker et al. shows the invention substantially as claimed including a pedestal for supporting a substrate 104 during plasma processing, the pedestal comprising: an electrode 108 configured generating an electric field; a chuck 106 disposed above the electrode, the chuck being configured for holding the substrate and having an outer periphery that is smaller than an outer periphery of the substrate (see fig. 2); an edge ring 114 disposed above the electrode, the edge ring being configured for shielding the

electrode and the chuck, and including a first portion configured to be disposed between the electrode and the substrate when the substrate is held by the chuck (and configured to surround an outer edge of the chuck) and a second portion being configured to surround an outer edge of the substrate when the substrate is held by the chuck for processing whereby the edge ring cooperated with the chuck to form a recessed portion for accepting the substrate for processing (see fig. 1); and an impedance matching layer 112 disposed between the electrode and the edge ring, the impedance matching layer made of a dielectric material such as SiC. It should be noted that the impedance. matching layer 112 will control the impedance between the electrode and the plasma. and will reduce the variations of the electric field. Furthermore, note that the chuck is disposed in an inner region of the electrode, the edge ring is disposed above the outer region of the electrode and positioned next to a side of the chuck, and the impedance matching layer is disposed between the edge ring and the electrode and above the outer region of the electrode. For a complete description, see for example, fig. 1 and its description).

Wicker et al. further discloses that the chuck, the edge ring and the impedance matching layer are made of a dielectric material, but does not expressly disclose that the dielectric constant of the edge ring is equal to the dielectric constant of the chuck, wherein the dielectric constant of the impedance matching layer is different than the dielectric constant of the edge ring and the chuck, and wherein the impedance matching layer is arranged to adjust an impedance produced through the edge ring so that it is substantially the same impedance as an impedance produced through the chuck.

Art Unit: 1763

However, it would have been an obvious choice of design to one having ordinary skill in the art at the time the invention was made to choose the same or different materials for the chuck, the edge ring and the impedance matching layer based upon a variety of factors, including for example, the plasma resistance of the material, and such limitation would not lend patentability to the instant invention absent the showing of unexpected results.

Regarding claims 36-37 and 41, note that the impedance matching layer is bonded to both the edge ring and the electrode, the electrode has an outer periphery that is greater than the outer periphery of the substrate when the substrate is disposed on the chuck for processing.

With respect to the impedance matching layer being bonded to the edge ring through a silicon elastomer, it would have been obvious to one of ordinary skill in the art at the time the invention was made to bond these elements through a silicon elastomer because this is a well established means of bonding elements in a plasma processing apparatus.

Claims 44-45 and 68 are rejected under 35 U.S.C. 103(a) as being unpatentable over Wicker et al., U.S. Patent 6,129,808, as applied to claims 32, 34-37, 39, 41-43, 47, and 67 as above, and further in view of Masuda et al., U.S. Patent 6,171,438.

Wicker et al. is applied as above but does not expressly disclose a heat transfer system as claimed. Masuda et al. discloses a plasma processing apparatus comprising a pedestal including a heat transfer system for controlling the temperature of the

Art Unit: 1763

substrate and the edge ring during processing, the heat transfer system including a first channel extending through the electrode to the interface between the chuck and the substrate, and a second channel extending through the electrode to the interface between the electrode and the edge ring, the heat transfer system being configured to provide a heat transfer medium though the channels, wherein the heat transfer is a helium gas (see fig. 2 and its description). Therefore, in view of this disclosure, it would have been obvious to one having ordinary skill in the art at the time the invention was made to modify the apparatus of Wicker et al., as to comprise the heat transfer system disclosed by Masuda et al. because this allows for effective and efficient temperature control of the substrate and the edge ring without incorporating a complicated mechanism.

Claims 60-61 are rejected under 35 U.S.C. 103(a) as being unpatentable over Wicker et al., U.S. Patent 6,129,808, as applied to claims 22-23, 25, 27-31, 48-49, 51-55, 63, and 65-66 as above, and further in view of Masuda et al., U.S. Patent 6,171,438.

Wicker et al. is applied as above and further discloses that the electrode is made of a conductive material and the edge ring and the impedance matching layer are made of a dielectric material (see col. 6, lines 15-23). However, the reference does not expressly discloses that the chuck is made of a dielectric material. Masuda et al. discloses an apparatus comprising a pedestal having an electrode formed of a conductive material, and having a chuck, an edge ring, and an impedance matching layer made of a dielectric material (see, for example, col. 8. lines 44-63). Therefore, it

would have been obvious to one having ordinary skill in the art at the time the invention was made to modify the apparatus of Wicker et al. as to comprise a chuck made of a dielectric material because such material is a suitable material for the chuck. With respect to claim 61, note that Masuda discloses that the edge ring and the chuck can be made of the same material such as alumina and the impedance matching layer can be made of a material having a larger dielectric constant such as SiC.

Response to Arguments

Applicant's arguments filed 5/6/05 have been fully considered but they are not persuasive.

Applicant argues that Ohmi, Masuda and Wicker do not teach or suggest regions having different impedances. The examiner respectfully disagrees because the impedances will be different since different materials are present in the different regions.

Furthermore, with respect to applicant's argument that Ohmi, Masuda and Wikcker fails to disclose an impedance matching layer configured to adjust the second impedance such that the second impedance is substantially equal to the first impedance, it should be noted that the presence of the impedance matching layers in the respective references will control the impedances and therefore the impedances will be substantially equal in comparison to the case in which there is no impedance matching layer. Additionally, note that Ohmi discloses adjusting different characteristic of the impedance layer in order to adjust the impedance (see, for example, paragraph 0036).

Art Unit: 1763

Concerning claim 48, note that as broadly claimed Ohmi does disclose the impedance matching layer be contained in the second zone.

Applicant argues that Masuda fails to teach an impedance matching layer being substantially planar. The examiner kindly disagrees since layer 132 in the Masuda apparatus can be considered an impedance matching layer because the layer 132 in Masuda is made of similar materials as the impedance matching layer of the instant invention. Furthermore, the portion of layer 132 that acts as an impedance matching layer is planar.

Applicant argues that Wicker fails to teach or suggest an impedance matching layer being substantially planar. The examiner kindly disagrees since layer 132 in the Masuda apparatus can be considered an impedance matching layer because the layer 132 in Masuda is made of similar materials as the impedance matching layer of the instant invention. Furthermore, the portion of layer 132 that acts as an impedance matching layer is planar.

Conclusion

Any inquiry concerning this communication or earlier communications from the examiner should be directed to Luz L. Alejandro whose telephone number is 571-272-1430. The examiner can normally be reached on Monday to Thursday from 7:30 to 6:00.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Parviz Hassanzadeh can be reached on 571-272-1435. The fax phone

number for the organization where this application or proceeding is assigned is 571-273-8300.

Information regarding the status of an application may be obtained from the Patent Application Information Retrieval (PAIR) system. Status information for published applications may be obtained from either Private PAIR or Public PAIR. Status information for unpublished applications is available through Private PAIR only. For more information about the PAIR system, see http://pair-direct.uspto.gov. Should you have questions on access to the Private PAIR system, contact the Electronic Business Center (EBC) at 866-217-9197 (toll-free).
